Two Kitchen Tricks That Feed Your Own GLP-1

The resistant-starch secret hiding in food you already eat

The one-minute why. Your body makes its own GLP-1, the appetite-and-blood-sugar hormone the famous injections imitate. One of the most reliable ways to nudge your own production costs nothing and hides in food you already eat. It comes down to a special kind of fiber called resistant starch. You do not digest it the usual way. It travels intact to your large intestine, where the bacteria you have carried your whole life ferment it into short-chain fatty acids, and those compounds signal the cells in your gut wall that release GLP-1 and its partner PYY. More resistant starch on the plate, gently and steadily, means more of the raw material your own hormone runs on.

Two everyday tricks change how much resistant starch your food actually delivers. Neither asks you to buy anything new.

Trick one: reach for the greener banana

A banana that is still a little green and firm, before the sweetness fully arrives, is packed with resistant starch. As it ripens to soft and spotty, that starch turns into ordinary sugar. So the same fruit can be a slow, gut-feeding food or a quick sweet one, depending on the day you eat it. If you are choosing a banana with your own GLP-1 in mind, take the underripe one and let the spotty ones go to the smoothie or the bread. Sliced firm green banana over oats is one of the simplest ways to stack two of these fibers in one bowl. A barely-ripe plantain works the same way.

Trick two: cook it, then cool it

This one turns leftovers into an upgrade. When you cook a starchy food like potatoes, rice, or pasta and then chill it in the refrigerator, the starch reorganizes itself as it cools. The molecules lock into a form your digestive enzymes struggle to break apart, so the cooled food carries more resistant starch than it did steaming hot off the stove. Cold potato salad, a rice salad, pasta salad, or potatoes boiled the night before all deliver more of this fiber than the hot version. And the kindest part: much of that resistant starch survives gentle reheating, so you can warm yesterday's rice and still keep a good share of the benefit. Batch-cook, chill, and eat from the refrigerator across the week.

Your resistant-starch grocery short list

- Green, firm bananas, and barely-ripe plantains
- Potatoes, rice, and pasta, cooked then cooled (reheat gently)
- Beans, lentils, and chickpeas of every kind, among the richest sources going
- Whole oats, especially left to soak overnight
- Cooked-and-cooled sweet potato and barley

How to use it this week (pick two)

- Cook a pot of rice or potatoes tonight and refrigerate half for tomorrow.
- Add a scoop of beans or lentils to one meal a day.
- Keep firm green bananas on the counter and slice one over breakfast.
- Make overnight oats and top them with green banana.

How much this really does

This is real, and it is gentle. Resistant starch feeds the system that makes your GLP-1, and the sturdier benefits show up when it becomes a steady habit rather than a single heroic meal. Add fiber gradually, and drink water as you do, or your gut will let you know. Think of it as a patient daily practice, one of the most affordable ways to keep your own hormone humming. It is not a drug, and it does not need to be.

Want the whole picture — food, gut, movement, sleep, the medicines, and how to decide? It is all in **Your Body's Own GLP-1** by Rev. Dr. LaVeena B. Archers.

Education and support, not medical advice. Every decision about a medicine belongs with you and your own prescriber.
